ABSTRACT

U.S. ships are provided onboard spare parts for equipment the ship's force is capable of repairing while at sea. The range and depth of spares provided has a pronounced effect on the availability of both ship and weapon systems. The spares suite for a particular ship is the Coordinated Shipboard Allowance List produced by the Ship's Parts Control Center. A mathematical model is used to produce this list, aiming to achieve stocking goals set by the Navy. This thesis examines the relationship between these goals and the model in use. A simulation model developed by the Naval Sea Systems Command has been modified so that it is compatible with the Naval Postgraduate School computer system, and this simulation model is used to evaluate the provisioning models. This simulation model is capable of being used for a variety of other projects at the Naval Postgraduate School.

I. INTRODUCTION

The capability of a modern warship to be combat ready and maintain this readiness over a deployment period depends on logistics support. While this support includes such necessities as food, fuel, medical supplies etc., a crucial element in maintaining the sophisticated shipboard systems is the availability of repair parts. More important, of course, is the necessity of having a skilled technician capable of diagnosing any problems and effecting the required repairs. This thesis will focus entirely upon the 'part' side of this two-way problem, knowing full well that the desired technical expertise is not always available on all ships.

To provide for the capability of repairing equipment while away from port or support ships, each ship is provided a quantity of spares designed to enable it to be self sufficient for a period of 90 days. Budget and storage constraints prohibit stockpiling spares to cover all possible requirements, therefore a choice must be made as to the method to allocate the range and depth of spares to be provided.

Chapter II discusses the way the Navy is currently making this allocation. The method has been successful for a number of years, but less so recently due to changes in

provisioning model parameters. These changes were dictated by the 'high cost' of the allowance list generated by previous parameters.

Chapters III, IV, and V describe the use of a reliability block diagram simulation program to evaluate the effect of changing the spares suite upon the reliability/availability of a shipboard system over a 90 day period with no external spares replenishment. To obtain an upper bound on the spares effectiveness, the 90 day period was simulated with all repairs being instantaneous; thereby placing the entire burden of making the system available on the spares suite and not upon the speed of the repair. From this technique a measure of effectiveness of each given spares suite can be derived.

As an example, a particular reliability block diagram is analyzed in chapter VI using the simulation technique. The nature/configuration of this block diagram has a large effect on the figure of merit results. For example, three different items connected in series would be less reliable than the same three connected in parallel where only two are required to be functioning at once and the third was in cold standby. It is for this type of reason that a provisioning process based on parts counting rather than reliability may provide satisfactory results for one system and unsatisfactory results for another when both systems possibly consist of the same piece parts or perform the same function.

The simulation (called TIGER) is a general reliability simulation model and is capable of many other uses besides the one chosen for this thesis. With the help of the appendices, the program listing, and the TIGER manual (Ref. 1) further use of this program on the Naval Postgraduate School (NPS) computer system or any other FORTRAN IV compatible system with random number generation capability should be feasible.

II. THE COORDINATED SHIPBOARD ALLOWANCE LIST (COSAL)

A. NAVY POLICY FOR PROVIDING SUPPLY SUPPORT OF THE OPERATING FORCES

The amount of logistic support required to support the desired levels of fleet readiness are delineated in Ref. 2. Of concern here are the sections on Shipboard Stock Levels and Criteria for Shipboard Allowances.

All non-Fleet Ballistic Missile (FBM) self-sustaining ships have a stockage objective of 90 days, which is equated to the endurance for the ship. This objective is applicable to repair parts, spares, and equipment related consumables.

The specific criterion for developing a COSAL from a list of those items capable of being repaired by shipboard personnel is the subject of the next section of this thesis.

The measures of effectiveness for COSAL performance as stated in Ref. 2, are to 'fill from onboard stocks 65% (gross effectiveness) of all demands and to provide an overall availability for items allowed to be carried of 85% (net effectiveness)'. It is essential to note that no mention is made of such terms as reliability, availability, or readiness in the context of the supported ship as a measure of COSAL effectiveness.

Net effectiveness is often called 'system' effectiveness, in that it is the effectiveness of the entire logistics

system in replenishing shipboard spares once they are used and reordered. As this is not specifically related to the COSAL provisioning document, but is a function of such diverse items as order and shipping times, specific examination of this measure will not be attempted. Rather, certain stated assumptions will be made regarding the percentage of spares onboard when it is necessary to do so.

The objective of 65% gross effectiveness is the central issue which this thesis will focus upon. As will be shown in the next section, the COSAL mathematical model in no way can be substantiated as a '65% gross effectiveness model'. More important is the question of '65% gross effectiveness' as a measure of effectiveness for shipboard support. One could conceive of ways to fill 75% of the requisitions received in 90 days from shipboard stock and never be able to get underway. Alternatively, a low fill rate could result in a highly successful deployment. The key, obviously, is to stock those items which are important to the ships mission, and not to stock simply to maximize stock turn.

B. CURRENT COSAL MATHEMATICAL MODELS

Several mathematical models are currently being used to generate COSALs. The Fleet Logistic Support Improvement Program (FLSIP) model is used for surface ships and Fast Attack Submarines (SSN) and is the most extensively used technique. The TRIDENT model is used on Fleet Ballistic

Missile Submarines (FBM) and is similar to the Maintenance Criticality Oriented (MCO) COSAL being implemented on the FFG-7 Lo-Mix class of ships.

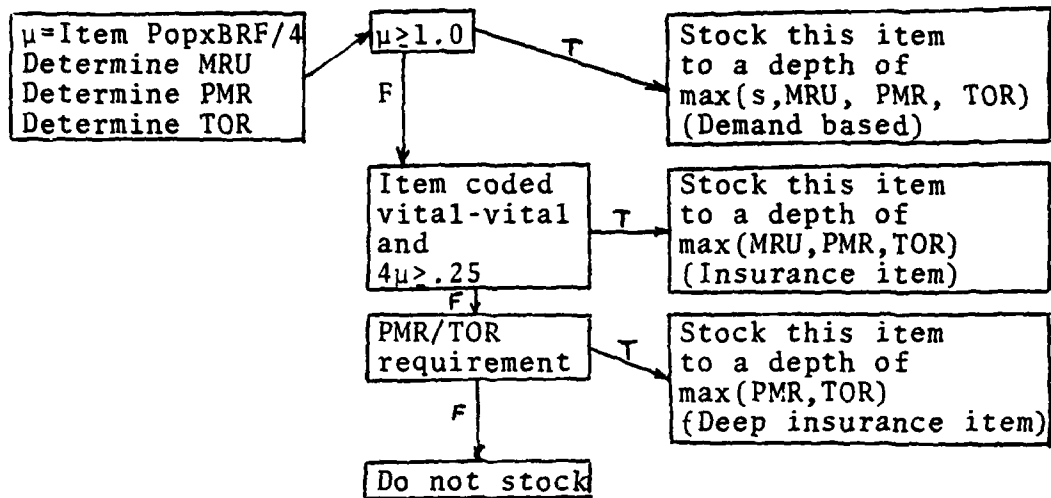

1. FLSIP Model

The FLSIP model has been in use for many years and has proven to be a rapid, workable, and understandable method of generating the large quantity of COSALS that must be run (approximately 50 per month). This model simply processes a list of all repair parts applicable to the particular ship and capable of being replaced by the ship's force. Each part is individually totaled for its' entire installed shipwide population and then is multiplied by its' Best Replacement Factor (BRF) (explained in chapter IV). The resultant value is called the 'mean', and this mean is used with the essentiality of the parent equipment to determine the final allowance quantity. A FLSIP logic diagram is shown in figure 1.

The attempt to incorporate essentiality into this model has been negated by the migration of over 90 percent of the parts on file into the 'vital' category. Technical Overrides (TORS) have been frozen by the Chief of Naval Operations (CNO) as a cost reduction measure.

The currently used model is called a .25 FLSIP model since the insurance cut point is .25 (one expected demand in four years). As over 90 percent of the items stocked on-board a ship are stocked at a depth of one, this cut point is critical to the ability of the model to provide sufficient

FLSIP COSAL LOGIC

Definitions:

Item Pop - Consolidated population of the item throughout the ship's systems

BRF - Best replacement factor

s - minimum stocking depth such that
Pr (Actual 90-day demand ≥ s) ≈ .90
(Assuming Poisson distribution)

MRU - Minimum replacement 'unit'
quantity, if any

PMR - Required preventative maintenance
quantity for planned maintenance

TOR - Technical override quantity, if any;
determined by engineers/designers
during equipment provisioning review

Vital-Vital code - Item vital to its parent
component, and its component vital
to a primary mission

Figure 1

support. This cut point was changed from a previous value of .15 due to various budgetary pressures.

Aside from the arbitrary nature of the value chosen as the cut point the main problems which continue to exist are the effectiveness criteria established in Ref. 2 and the fact that the FLSIP model (Figure 1) has no mathematical relationship to these criteria. If the FLSIP is to be continued in use, and indications are that it will (Ref. 3), meaningful effectiveness criteria must be established and a means developed to justify the use of the FLSIP model to meet these criteria.

2. TRIDENT Model

The TRIDENT model incorporates military essentiality codes (MEC) assigned to the parent equipment into the stockage allowance decision. The more essential the equipment, the better it will be supported. The following equation is used to calculate the allowance quantity:

$$\text{Allowance quantity} = \mu + (Zx\mu)$$

Where μ is the mean of the assumed Poisson distribution of repair part requirements in 90 days).

The multiplier Z is a function of essentiality and to a lesser degree the unit price of the part. As in the FLSIP model each candidate part is processed individually and is not subject to budget constraints (although the levels may be adjusted through the manipulation of the various factors which comprise Z).

This model is currently in use; takes essentiality of equipment into account; and provides excellent support. But as could be expected, the resulting COSAL provides generous allocation of spare parts and its cost would be hard to justify outside of the FBM arena.

3. Maintenance Criticality Oriented (MCO) Model

The MCO model is an allowance list to be implemented on an increment of the new FFG-7 Lo-Mix class of ships. The mathematical technique is very similar to the TRIDENT model, the main difference being that essentiality is carried all of the way to the part level. The documentation required to achieve this is extensive and costly and must be maintained throughout the life of the ship. The documentation required to backfit the MCO model to older classes of ships does not exist.

III. THE NAVAL SEA SYSTEMS COMMAND TIGER SIMULATION PROGRAM

A. INTRODUCTION

TIGER is the generic name for a family of computer simulation programs which can be used to evaluate a complex system in order to estimate various reliability, readiness, and availability measures. This program was developed by the Naval Sea Systems Command (NAVSEA) reliability branch. The reliability block diagram of the system/component under study is the foundation from which a TIGER simulation run is constructed. This block diagram may be for a large system (ship) with each block representing a component of the system; or it may be for a single component with each block representing a lowest replacement unit part; or the block diagram may be any type of combination of both. As an input for each block the Mean Time Between Failures (MTBF) and Mean Time to Repair (MTTR) must also be known.

The unique feature about TIGER is the flexibility incorporated into the program. Scenarios with block diagram configurations which change during the time period being simulated are evaluated through a series of different time-line 'phases' in the input. A phase is a specific reliability configuration for the ship being studied. The simulation will accept up to six different phases, and they may be sequenced in any order and be of any interval of time. The

phases may be strung together until the simulation capacity of 95 total phases is reached. MTBF, MTTR, and spares multiplier factors may be entered to perform sensitivity analyses on the system under study.

TIGER uses Monte Carlo random number methods to evaluate the input block diagram. The random numbers are generated through the use of the NPS LLRANDOM routine (Ref.4).

The TIGER simulation is a discrete event step simulation. Exponential failure and repair times are generated using the MTBF and MTTR input data. As equipments fail spares are used; repairs effected (if allowed in the phase); standby equipment turned on/off if required; and different block diagrams initiated as the different phases are encountered during the timeline. Statistics are collected as a result of each event and change of configuration.

The TIGER output includes estimates of reliability, readiness, availability, and critical components which caused the most severe degradation of reliability and availability. The user may change the random number seed and replicate a timeline as many as 1000 times in a single TIGER run. TIGER will calculate and provide a lower confidence limit for the point estimate of reliability.

The inherent limitations to the use of this type of simulation include both the problem of providing accurate input data (MTBF, MTTR) and the exponential failure/repair rate assumption used in the program. Under many scenarios and for many types of equipment this exponential assumption is valid

but certainly many types of equipment exhibit wearout and not all repair times are exponentially distributed.

In addition to the output mentioned above, spares usage may also be displayed as well as several standard and optional outputs of the progress of the simulation. The detail can vary from every event being shown to a much simpler management summary.

Two subroutines of TIGER were omitted in this thesis research but may be useful in different types of analysis. One of these, the GAMMA option, assumes that the system being evaluated has a gamma failure distribution and calculates the two parameters (shape and scale) for the gamma distribution which would exhibit the same mean and variance of mission failure times as the system being modeled. The DEMO option of TIGER provides the capability of generating a sequential probability test ratio plan for the system as prescribed in MIL-STD-781. Detailed information about TIGER including GAMMA; DEMO; and a TIGER/MANNING personnel requirements type program is found in Ref. 1.

B. PRESENT NAVSEA TIGER UTILIZATION

The TIGER program is being used by NAVSEA to evaluate Reliability, Maintainability, Availability (RMA) performance characteristics of new ship classes (Ref. 5). This analysis is performed only on the major mission-essential systems: Navigation, Auxiliary, Electrical, Ship Control, Propulsion,

Exterior Communications, and Combat. Only these systems and equipment which impact the operational readiness of the ship and the ship's ability to perform its assigned primary combatant mission are included in the analysis.

All surface ships constructed since 1970 have reliability block diagrams available (in computer readable form). This eliminates the major undertaking of having to construct the reliability block diagrams prior to using TIGER. The necessary MTBF and MTTR data for existing equipment is found in the Reliability/Maintainability/Availability Design Data Bank (Ref. 6), which is a compilation of data from both engineering design and fleet feedback. Engineering estimates must be used for the many new systems found on a new class of ship, where no feedback data yet exists.

Along with the various reliability block diagram configurations (steaming, in-port, ASW, etc.) and MTBF/MTTR data, the operating rules for the equipment must also be provided. These rules include allowable downtime, spares, mission timelines, and maintenance policy.

A sample RMA timeline (Ref. 5) is shown in figure 2. Timelines are tailored to the class of ship and its designed usage in a period of combat.

Allowable downtime is the time that the system or equipment can be down for maintenance without causing a mission abort. During simulated combat periods this time is usually zero for most mission essential systems.

Maintenance policy limits certain equipment to being capable of repair only during certain phases. For example, repair of the main engine would not be permitted while hunting a submarine, but would be permitted while in-port.

Spares are assumed to be available as needed for initial TIGER analysis. Supportability tradeoff studies are conducted separately to evaluate the effect of different spares efficiency percentages and off-ship logistic delay times.

The results of the TIGER simulation are compared with design specifications to see if any inherent (non-spares related) reliability problems exist. Critical equipments are then identified and closely monitored during the final phases of design and construction.

C. PROPOSED TIGER UTILIZATION FOR COSAL PREPARATION

Reference 7 describes a methodology of using the TIGER program to evaluate a COSAL with respect to reliability. The inputs to the TIGER program would be the same as those in the last section with the exception of the spares input and the indenture level of the reliability block diagram. The diagram must not stop at the equipment level, but be carried out to the repair part level. MTBF/MTTR data must also be provided at the repair part level.

As may be readily apparent, the block design for just the essential equipment of an entire ship would be very cumbersome and unworkable. This type of TIGER analysis must

be done on a system or equipment basis. The spares input would be that generated by the COSAL model under evaluation, usually FLSIP.

A deployment timeline is simulated and the resulting reliability/availability figures are compared to the design goals. If the goals are not achieved the 'bad apples' list of repair parts indicates the particular parts which caused the most degradation. Additional quantities of these parts are added to the spares suite and the process is repeated until the goal is attained. This method may also be used in reverse, removing spares and observing the resulting changes to reliability/availability.

While this methodology is feasible and would certainly provide better support than an unaugmented FLSIP COSAL, it has several drawbacks. One is the lack of reliability block diagrams down to the repair part level. Although new equipment procurement contracts may specify that this documentation must be provided, the task of assembling it for just one ship's essential equipment would be awesome.

Another problem is the lack of MTBF/MTTR data for each part. Reference 8 may be used to estimate the required parameters, but again this is a large undertaking. As was mentioned earlier in this thesis, current provisioning processes use a BRF vice MTBF to determine logistic support. A further clarification of the differences between these two and a proposed solution will follow in a later section.

A final problem results from the fact that repeated computer runs on a vast network of reliability block diagrams are required to produce a single COSAL. The computer system at the Ships Parts Control Center (SPCC) is saturated and could not begin to process the large quantity of simulation runs necessary to use this proposed method on all COSALs. In addition, a significant number of manhours would be required to review each run and decide which parts to augment and in what quantity. Though this process would undoubtedly produce a COSAL superior to the FSLIP model, practicality prevents its adaption at the present time.

IV. BEST REPLACEMENT FACTOR (BRF)

A. BRF - WHAT IS IT?

The BRF is the projected annual replacement rate for one installed unit of a repair part. Only one BRF exists for each part even if it is used in numerous applications throughout a given ship or the fleet or ashore. The BRF is found by dividing the annual reported usage in the fleet by the total installed population. This yields annual failures per installation. Before any calculations are made the input data are adjusted for inaccuracies caused by bad reporters and inactive ships in overhaul. The BRF is calculated annually for each item in the SPCC files. To prevent rapid fluctuations from occurring the previous value on file is updated with the new value by the use of exponential smoothing.

To illustrate this process suppose that 105 ships in the fleet were each recorded as having two of part 'A' installed. Five ships were in overhaul for this particular year so their data is not used for BRF update. The remaining 100 ships reported a total of 400 failures for item 'A'. Since there are 200 of 'A' installed and 400 were used, the unsmoothed BRF is $400/200 = 2.0$. If the BRF currently on file is 2.4 and exponential smoothing with smoothing constant .25 is used, the updated BRF would be $2.4 \times .75 + 2.0 \times .25 = 2.3$.

This BRF would be put on file for use in all COSALS which contain part 'A'.

B. MEAN TIME BETWEEN FAILURE (MTBF)

MTBF is the expected value of the operating time between failures of an item. It is estimated by dividing the total time in service by the number of failures:

$$\text{MTBF} = \text{total time in service} / \text{number of failures}$$

Sometimes the expression Mean Time to Failure (MTTF) is used for the expected value. Another related measure is the failure (hazard) rate which is the conditional probability that an item surviving to age t will fail in the interval $(t, t+dt)$. A constant failure rate is equivalent to having a failure distribution which is exponential; and for an exponential distribution the failure rate is the reciprocal of MTBF.

C. DIFFERENCES BETWEEN MTBF AND BRF

A MTBF provides an expected value of the length of time an item will operate until failure. It is based on operating time; and failures are not possible while the equipment is not in use or turned on. A BRF is the average number of times an item will fail in an average year in an average installation. Since these differences and similarities are crucial to the analysis in section VI of this thesis, the following example taken from Ref. 9 provides an insight into the MTBF/BRF relationship.

A piece of equipment (lamp) has four repair parts (bulb, socket/switch, cord, plug). It is operated for 1000 hours per year. An arbitrary MTBF and corresponding Failure Rate (expressed in failures per year) are shown below:

ITEM	MTBF	FAILURE RATE
Light Bulb	750 HRS	1.333
Socket/Switch	10,000 HRS	0.100
Electric Cord	15,000 HRS	0.066
Plug	10,000 HRS	0.100
TOTAL		1.599

As shown, the lamp is expected to fail 1.599 times per year. This would be a BRF for the lamp if the maintenance policy were to replace the whole lamp no matter what the cause of the failure. The following table shows how maintenance philosophy can have a pronounced effect on the five BRFs. The 'Replace Failed Part' column represents the way repairs are usually accomplished at the shipboard level. Only catastrophic failure would lead to the attempted replacement of the entire item, usually unsuccessful because the entire assembly would not likely be stocked due to the low BRF.

ITEM	FAILURE RATE PER YEAR	MAINTENANCE PHILOSOPHY		
		REPLACE FAILED PART	REPLACE LAMP	REPLACE FAILED BULB, OTHERWISE REPLACE LAMP
LAMP	1.599	BRF=0.	BRF=1.599	BRF= .266
BULB	1.333	BRF=1.333	BRF=0	BRF=1.333
CORD	0.066	BRF=0.066	BRF=0	BRF=0
S/SWITCH	0.100	BRF=0.100	BRF=0	BRF=0
PLUG	0.100	BRF=0.100	BRF=0	BRF=0

D. BRF AS AN INPUT TO TIGER

When MTBF is used as an input to TIGER, various timelines are used to provide scenarios in which the equipment configurations and usage rates are required. When equipment is on, it fails exponentially with the given MTBF, unless the duty cycle is less than 100 percent, in which case the MTBF is divided by the duty cycle. The BRF has incorporated the various reasons the timeline approach must be used with the MTBF; equipment being turned off and on; duty cycles for equipment with cycles of less than one; and the various configuration dependent usage rates for an average installation in an average year.

Consider, for example, an equipment with a duty cycle of one-half (operating 50 percent of the time) exhibiting five failures in a ten year period. The MTBF is calculated as before; $\text{total time in-service/failures} = (10 \times .5) / 5 = 1 \text{ year}$. Since the duty cycle is one-half, we would expect to see a failure every other year, or .5 per year. The BRF calculation yields the same result; $5 \text{ failures} / 10 \text{ years} = .5 \text{ failures/year}$.

To use a BRF in TIGER requires that the entire block diagram, in a typical configuration, be used and equipment/parts be allowed to fail at an annual rate (BRF) which takes the numerous operating scenarios into account. While the results from this type of analysis would be very difficult to defend as providing entirely accurate reliability/

availability measures; they should be suitable for deriving a 'figure of merit' evaluation for the support provided by different COSAL models.

V. TIGER USED TO EVALUATE THE EFFECT OF SPARES ALLOWANCE
POLICY UPON RELIABILITY AND AVAILABILITY

A. INTRODUCTION

The current utilization of gross effectiveness as a measure of COSAL effectiveness has been studied in previous sections. An alternative measure will now be proposed. The TIGER program calculates reliability, availability, and readiness figures for each simulation run. The definitions for these three measures, as found in Ref. 1, are summarized below.

B. RELIABILITY (REL)

For a given timeline the reliability (REL), as estimated by TIGER, is the probability that the ship will successfully complete the entire timeline. For example, if the timeline previously shown in figure 2 were used, REL would be the probability of the ship completing all of the different missions assigned during the 60 day period, in the sequence shown.

Reliability is calculated by TIGER as follows:

$$\text{REL (EST)} = 1 - \frac{\text{Number of mission failures (aborts)}}{\text{Total number of simulated missions}}$$

Note that this calculation incorporates logistics support considerations.

C. AVAILABILITY (AVA)

TIGER calculates two AVA parameters: Instantaneous and average. Instantaneous availability is the probability that the system will be 'up' at a specific point in time. Average availability is the probability that the system will be up at a random point in time. Because of the way TIGER is used, average availability is the relevant measure.

Average AVA is estimated as the ratio of total system 'uptime' to the total time simulated. These times are totaled for the entire number of missions simulated (up to 1000). The calculation is made as follows:

$$\text{AVA (EST)} = \frac{\text{Summation of uptime for all missions simulated}}{\text{Summation of total mission calendar time for all missions simulated}}$$

$$= \frac{\text{Uptime}}{\text{Calendar time}}$$

D. READINESS (RED)

RED, like AVA can be measured as instantaneous or average readiness. It is a measure of the probability that there is neither a mission abort nor a system down. The forthcoming methodology for the use of TIGER results in RED equaling AVA, so RED will not be considered any further as an alternative measure of effectiveness.

E. RELIABILITY VS AVAILABILITY AS A MEASURE OF EFFECTIVENESS

A very common measure of effectiveness in use by the Navy today is 'Operational Availability' (Ao). Ao is defined as the probability that an equipment is ready when you need it. MIL-HDBK-217C (Ref. 8) dictates that it be calculated by:

$$Ao = \frac{MTBF}{MTBF + MTTR}$$

An alternative form of this equation results from breaking the MTTR up into the repair time (MTTR) plus the Mean Supply Response Time (MSRT); the time necessary to provide the required repair part(s). This yields:

$$Ao = \frac{MTBF}{MTBF + MTTR + MSRT}$$

There are problems with the use of this formula for estimating system operational availability (Ref. 10). From a mathematical point of view the formula yields the correct result for the limiting value of operational availability when one considers a single component that transitions between up and down states as an alternating renewal process. If one is interested in the operational availability after a fixed period of time for a system whose components have limited spares support, the formula does not yield correct results. In fact, the formula makes little sense. A simulation like TIGER is precisely what is needed to estimate Ao for a complex system with limited spares support.

Since AVA implicitly considers component reliability, maintenance, spare parts support, system configuration and

operational scenario, it is used in this thesis to evaluate COSAL models.

F. ALLOWANCE POLICY EFFECT

1. Reliability Block Diagram of System

The effect of a parts-counting type allowance policy upon reliability/availability is dependent on the configuration of the system being supported. Parts counting is a method of allocating spares in proportion to the number of each specific repair part in the equipment. In an environment of limited budgets and storage space, a more 'critical' spare (in terms of reliability/availability) may be sacrificed to provide unwarranted depth for another spare.

Figure 3 shows a simple reliability block diagram with two

Figure 3

of part A in parallel with each other and then in series with part B. Both A and B have a BRF of 1. If A cost the same as B, and only one spare could be provided, provisioning by parts counting would provide one spare of type A, since there are twice as many A as B. However, the availability of this system would be much greater (all other things considered the same) if the one spare purchased were of type B, due to the parallel redundancy.

2. Proposed Allowance Policy Input

There are two methods of entering the quantity of spares for each part type into the TIGER simulation. One is to input that quantity as part of the input data. For small systems this may be the most efficient method. For larger systems or for those systems requiring a complicated mathematical model, a subroutine has been added to TIGER to calculate the COSAL.

For the FLSIP COSAL, the cut point is input with the other system data and the spares subroutine is used to generate the COSAL for the system. The MTBF is derived from the BRF in the following manner:

$$\text{MTBF} = (1/\text{BRF}) \times 8766 \text{ (yr/fail)} \times (\text{hr/year}) = \text{hr/fail}$$

This MTBF is used as the exponential failure rate input for the simulation, and converted back to BRF when necessary to determine COSAL support.

3. Figure of Merit Results

Several simplifying assumptions are made by using TIGER to obtain the output availability measure. The most important are exponential failures; BRF converted to MTBF; zero repair times; a full allowance of spares onboard at the beginning of the mission; and the use of a 'typical' reliability block diagram configuration for the duration of a single mission. Because of these assumptions, the availability figure provided by TIGER should not be considered as the true value for system availability. However, this figure

should be useful as a 'Figure of Merit' for comparisons with the figure derived for the same system using a different methodology or level of logistics support. When used in this context, the figure should provide an accurate assessment of the relative effectiveness of two spares allowance policies.

VI. EXAMPLE OF TIGER ANALYSIS

A. EQUIPMENT CONFIGURATION AND FAILURE RATES

1. Block Diagram and Operating Rules

As an example of the use of TIGER proposed in this thesis a hypothetical video display unit will be analyzed. The unit consists of a power section; signal processing section; and video display section. The required reliability block diagram is shown in figure 4.

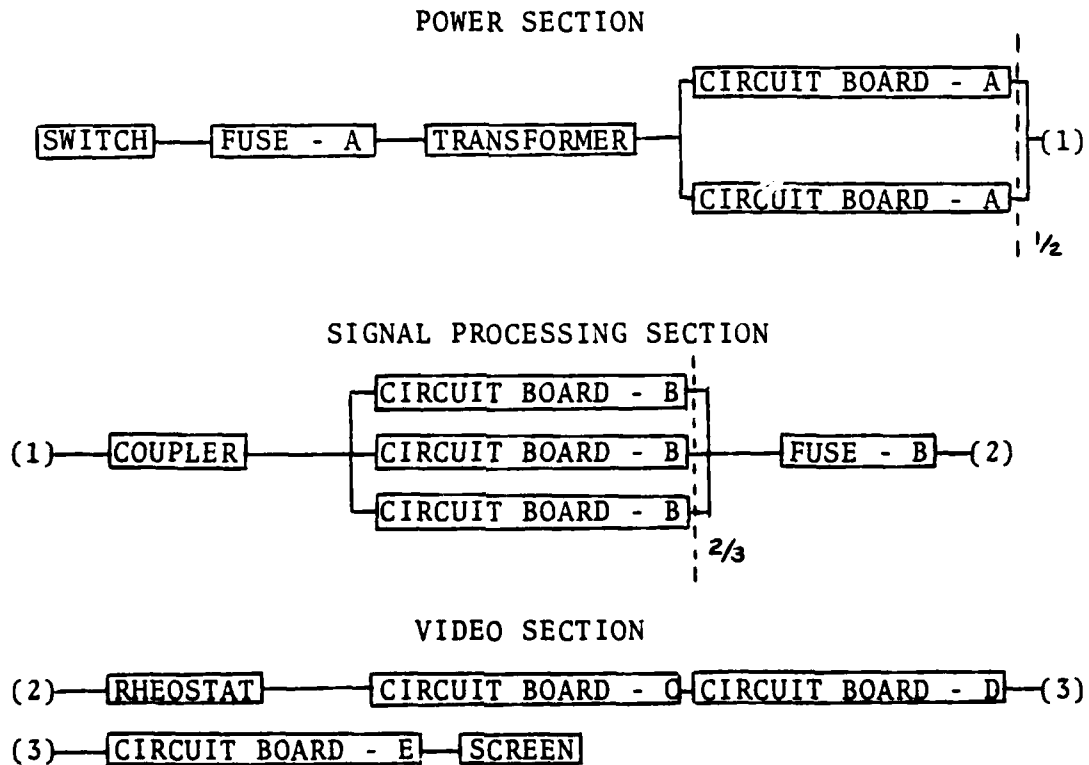

Figure 4

The three sections are connected in series to form the entire unit. Only one of circuit board A is required to be 'up' in the power section, and two of circuit board B in the signal processing section. The failure of two of either circuit board A or B or the failure of any other single part will cause system failure.

2. Failure Rates

The following is a list of the BRF for each part and corresponding MTBF:

<u>ITEM</u>	<u>BRF</u>	<u>MTBF</u>
Switch	.09	97400
Fuse - A	2.50	3506
Transformer	.17	51565
Circuit Board - A	2.10	4174
Coupler	.23	38113
Circuit Board - B	2.50	3506
Fuse - B	3.60	2435
Rheostat	.12	73050
Circuit Board - C	1.20	7305
Circuit Board - D	2.20	3985
Circuit Board - E	1.70	5156
Video Screen	.20	43830

B. LOGISTIC SUPPORT (COSAL) MODELS USED

The COSAL models evaluated were the standard .25 FLSIP and a modified FLSIP as proposed by the CNO Shipboard Parts Allowance Policy Study (Ref. 3). This modification consists of changing the FLSIP cut point to .1 (one demand in ten years) and providing an allowance quantity of two (vice one) for those items with a BRF between 2.0 and 4.0.

C. RESULTS OF ANALYSIS

1. Results of TIGER Simulation

The following tables provide a summary of the relevant output from the two TIGER simulation runs for 90 day missions. The actual computer output is self explanatory and a sample is included as a separate section of this thesis. The percent unavailability column indicates the percent of unavailability caused by each item.

.25 FLSIP (Availability = .7229)

ITEM	SPARES STOCKED	SPARES USED	FAIL/ MISSION	PERCENT UNAVA
Switch	0	.00	.025	3.35
Fuse - A	1	.50	.637	14.54
Transformer	0	.00	.042	6.42
Cir Bd - A	2	.96	1.05	6.77
Coupler	0	.00	.064	9.35
Cir Bd - B	4	1.84	1.897	.81
Fuse - B	1	.57	.793	24.01
Rheostat	0	.00	.030	3.74
Cir Bd - C	1	.27	.318	3.64
Cir Bd - D	1	.43	.541	11.99
Cir Bd - E	1	.34	.416	7.07
V. Screen	0	.00	.052	8.29
			<u>5.865</u>	<u>99.98</u>

.1 MOD FLSIP (Availability = .9064)

ITEM	SPARES STOCKED	SPARES USED	FAIL/ MISSION	PERCENT UNAVA
Switch	0	.00	.017	8.53
Fuse - A	2	.59	.607	5.41
Transformer	1	.05	.054	.75
Cir Bd - A	2	.92	1.015	24.70
Coupler	1	.06	.067	1.23
Cir Bd - B	4	1.84	1.897	2.58
Fuse - B	2	.79	.844	18.19
Rheostat	1	.04	.044	.00
Cir Bd - C	1	.27	.310	13.43
Cir Bd - D	2	.53	.553	5.42
Cir Bd - E	1	.35	.414	18.99
V. Screen	1	.04	.046	.74
			<u>5.868</u>	<u>99.97</u>

2. Interpretation of Results

As would be expected, the .1 Mod FLSIP provided a greater depth and range of spares than the .25 FLSIP. The addition of seven more spares resulted in an increase in AVA from .7229 to .9064, a significant increase. For the .25 FLSIP run, the item accounting for highest percentage of availability is fuse - B, with 24.01 percent. Since FLSIP provides a 90 percent confidence level of protection for those items with a BRF ≥ 4.0 ($\geq 1/\text{qtr}$), the BRF of 3.60 places the fuse just below this cut and therefore it is allocated only one spare. For the .1 Mod FLSIP run fuse - B no longer is the largest contributor to unavailability. Circuit board - A is the largest, accounting for 24.70 percent of the unavailability. If further incremental improvements were to be made to the .1 Mod FLSIP COSAL, the first additional spare should be circuit board - A followed by circuit board - B, fuse - B, and so on down the list of unavailability percentages.

The difference in AVA for the two COSALS is the most important statistic. If availability in the range of .9 were required for the system, the .1 Mod FLSIP should be used. If however, the system were not that essential, the .7 availability provided by FLSIP should be used to enable scarce spares funding resources to be used on more essential systems.

VII. SUMMARY AND CONCLUSIONS

This thesis focused on one basic problem; that of providing logistics support for Naval units afloat. Current guidelines and measures of effectiveness were presented along with several of the methodologies by which the policies are being carried out.

The NAVSEA TIGER reliability block diagram simulation program was introduced as a currently used method of evaluating ship reliability and also as a proposed method of generating allowance documents. A key input to any reliability calculation is the MTBF. The use by the Navy of a BRF vice MTBF was reviewed and a solution proposed to enable BRF to be used as an input to the TIGER simulation.

A technique for using TIGER to evaluate the effect of various spares allowance policies upon system availability was introduced, followed by an example of such an analysis.

The Navy is interested in providing logistics support so as to maximize the operational availability of its ships within given resource constraints. Mathematical models designed to allocate spares while maximizing system availability require extensive amounts of data (much of which is either not available or retrievable by computer). They are computationally infeasible to implement on a Navy-wide basis. Thus, it appears that the Navy will continue to use simpler

parts-counting models such as those described in this thesis. No claim of optimality with respect to 'system availability' can be made with such simple models that make no attempt to consider the system as anything other than a collection of parts.

The models that are being used are regulated by controlling the values of certain parameters such as FLSIP cut points or essentiality codes. Since there is no way to analytically relate these models to system effectiveness, a tool such as the TIGER simulator is needed to evaluate the future impact on system availability of a given provisioning or support policy. The assumptions required to perform this type of evaluation have been discussed throughout this thesis.

The following are recommendations for additional work in the topic of this thesis or for additional uses of the TIGER simulation:

1. Use as an evaluation tool for various provisioning models.
2. Use to evaluate maintenance policies and their effect on required manning levels.
3. Use as a system design tool.
4. Use on new equipment being introduced into the fleet to establish a FLSIP cut point. Code equipment with this cut point instead of the vital/non-vital codes currently in use, and use this cut point when preparing the COSAL.

5. Evaluate the effect of the assumptions made in this thesis and other problems such as the gradual degradation of equipment (not simply up or down) and the effect of the annual revisions to the BRFs.

APPENDIX A

ACRONYMS

Ao	Operational Availability
AVA	Availability
BRF	Best Replacement Factor
COSAL	Coordinated Shipboard Allowance List
CNO	Chief of Naval Operations
EST	Estimate
FBM	Fleet Ballistic Missile
FFG	Guided Missile Frigate
FLSIP	Fleet Logistics Support Improvement Program
MCO	Maintenance Criticality Oriented
MEC	Military Essentiality Code
MRU	Minimum Replacement Unit
MTBF	Mean Time Between Failure
MTTF	Mean Time to Failure
MTTR	Mean Time to Repair
NAVSEA	Naval Sea Systems Command
NPS	Naval Postgraduate School
PMR	Preventative Maintenance Requirement
RED	Readiness
REL	Reliability
RMA	Reliability/Maintainability/Availability

SPCC	Ships Parts Control Center
SSN	Fast Attack Submarine (Nuclear)
TIGER	Simulation Program Name
TOR	Technical Override

APPENDIX B

TIGER PROGRAM VARIABLES LIST

The following is a list of the variables used in the TIGER program and their respective usage/definition. All variables which were used in this thesis are included along with some from other optional parts of the TIGER program. Numbers at the right indicate the data card on which the variable is input into the program.

A	Subroutine DEMO producer risk	21A
ACMMH	Average corrective manhours per mission	
ADT	Administrative delay time	
AENDT1	Downtime in remainder of phase due to abort	
AENDT2	Downtime in remainder of mission due to abort (up to current phase)	
AFM	Average failures per mission	
ALDONE	Sum of three DONE(I); if zero, skips spare printout	
APPL	Bad apple unreliability and unavailability printout	21
AVA	Average availability or availability	
AVAINS	Instant availability	
AVA1	Average availability	
AVAL	Average availability	
AVGCST	Average cost per hour of repairman	7M
B	Subroutine DEMO consumer risk	21A

BAPRIN	Bad Apple printout indicator, when equals -1, print	
BILL	Temporary variable used to integerize the number of spares	
BLNK	Four character alphabetic blank	
COUNTB(I)	Number of failures for equipment I	
DAY(IX)	Occupation symbol	15A,M
DELT	Time Difference	
DEMO	Probability ratio test plan for system	21
DMNO	Same as DEMO	
DNT1	Total system downtime in phase	
DNT2	Total system downtime in mission	
DONE(I)	Average number of spares used from ship, tender, depot(I=1,3)	
DUM(J)	Dummy variable to read F1	
DUMMY	Skill types	
ENDPHA	End of phase time	
EQUIP(I)	Person type numbers of people who could be operating this type of equipment	15G
ETIME	Event time	
EX(I,J)	Administrative delay time (U,W)	
F(I,J)	Same as F1	
FCOUNT	Real value of JCOUNT	
F1	Alphabetic equipment description	8
GMMA	Alphabetic request for GAMMA subroutine	21
HAD	DEMO X-axis accept intercept	21A
HRD	DEMO X-axis reject intercept	21A
I	Various indices; equipment type number	8

IABC	Index	
IAUP	Instant availability (up for entire simulation)	
IAUP1(I)	Instant availability (up at beginning of sequence)	
IAUP2(I)	Instant availability (cumulative up at beginning of sequence)	
IB(I)	Group number and equipment and groups which make up the group	18
IBLANK	14 alphabetic blank spaces	
IBM	Equipment type number	
IBNUM(I,J)	Number of configuration matrix cards in phase	
ICHLD	Child in reliability tree	
ICRI	Subsystems exceeding mission allowable downtime (TAD2)	
ID	Alphabetic system name	16,17
IDIFF	Total equipment failures (all types)	
IDUM	Same as IUT	
IEQ	Absolute value of IEQU(J)	
IEQU(I)	Equipment type array	
IFF	Number of failures	
IFFEOP	Same as ISW	
IFLAG	Repair option in each phase	6
IFR	Number of repairs	
IGRP	Equipment group	
II	Spare location (ship, tender, depot)	
III	II-1	
IIUSED(I,J)	Spares used per equipment type from each location	

IK	Phase indicator	
IK2	Phase indicator	
IK3	Phase indicator	
ILB	Counter for NEQ	
ILL	Phase subscript for VDC(IU,ILL)	
IND	Equipment type	
INDEX	Index; equipment number	
INEWA	Index used to rank equipment by number of failures	
INMI(I)	Number of missions run	
INOABT(I)	Number of aborts in the sequence	
INREJ	Not used	
INUM	Maximum number of mission repetitions (50)	
IOR	Number of equipment operating rules	
IPTR	Parent/Child index	
IPRNT	Parent reliability tree	
IRULE	Equipment operating rule card	19
ISEED	Random number seed	2
ISO	+=string; -=standby	
ISPARE(I,J)	Quantity of spares at ship, tender, depot	15
ISS	System/subsystem identification number	16,17
ISSA(I)	Phase allowable downtime	
ISTB(I)	Equipment operating rules	19
ISUM	Summation	
ISW	Subsystem status (1=up, -1=down)	
ISSC	Subsystems exceeding allowable downtime	

ISYS(K)	System in phase K	
ITEMP	System status indicator	
ITEMP2	Subsystem status indicator	
ITIME	Number of sets	21A
ITER	Number of simulations per set	21A
ITOTAL	Integer value of total	
IU	Variable duty cycle (IUI(I))	
IUI(I)	Variable duty cycle indicator	8
IUNLIM	Alphabetic 'unlimited spares'	
IUT	Same as IDUM	
IUSED(I,K)	Spares used from ship, tender, depot	
IV	Variable duty cycle indicator (IUI=IV)	9
IVALUE(I)	Temporary variable for IB or ISTB	
IX	NUM+1	
IXX	Equipment type	
IXXT	Phase type	
J	Various indices; equipment type	
JA	Index for IB	
JB	Index for IB	
JBB	Phase sequence number	
JBB1	JBB-1	
JC	Current timeline	
JCC	Number of timelines	1
JCOUNT	Number of failed equipments	
JIND	Equipment type	
JNUM	Integer of XNUM	

K	Various indices	
KAA	Mission number being simulated	
KAB	Mission number being simulated	
KD	Trucation line accept	
KEQ	Equipment number	
KEQU(I)	Number of failures for equipment type I	
KID	Dummy variable	
KID1	Equipment group	
KID2	Equipment group	
KK	Same as LL; index of equipment number	
KKK	Phase in mission	
KKK2	Same as KKK	
KOPT	Printout option switch	5
KS(I)	Output options for KOPT	5
KSS	Index	
KT	IB(, ,1), or number required up in group	
K1	Equipment type; trail shape parameter	
L	Same as LL	
LCL	Lower confidence limit	
LL	Phase type number	16,17
LLL	Duration of phase sequence	
LOAD(I)	Equipment numbers assigned to equipment type	12
MAXIB	Maximum number of configuration matrix cards (300)	
MAXNEQ	Maximum number of equipments (500)	
MAXNPH	Maximum number of phases (6)	

MAXRUN	Maximum number of mission (1000)	
MAXSEQ	Total number of phases	
MAXSS	Maximum number of subsystems (31)	
MAXSTD	Maximum number of equipment operating rule cards (49)	
MAXTYPE	Maximum number of equipment types (200)	
MDT	Estimator of MTTR	
MKBA	Bad Apple equipment vector	
MM	0	
MTBMF	Mean time between mission failures	
MUT	Instantaneous MTBF parameter	
M1	Trial scale parameter	
N	Counter; NSS+1	
NEQ	Equipment type counter	
NLINE(I)	Number of configuration cards in phase	
NL1	NLINE(LL)	
NN	Index	
NMAX	Maximum number of missions	2
NOPT	Optimal number of mission	2
NPH	Number of phases	2
NRO	Number required operating	18
NSS	Number of subsystems in phase	16
NTY	Last number of equipment types	
NTYPE	Equipment type	12
NT1	Equipment type number	
NUM	Mission number counter	

PERC	Percent unreliable	
PL	Reliability specification	2
R	Dummy variable used to find next event temporary variable used to calculate VDC; discrimination ratio	21A
RDT	Running down time	
RED	Readiness	
REDAD1(I)	Adjusted time for readiness calculation in phase	
REDAD2	Adjusted time for readiness calculation in mission	
RED1	Readiness	
RED2	Readiness	
REL	Reliability	
RELGA(JBB)	Reliability (RELPY) for phase sequence	
RELPY	Reliability up to and including phase just completed	
REPOL	Percent of repairs performed aboard ship	7
RN	Random number	
RN3	Random number	
RUNID	Alphabetic program identification line	1
SLD	Slope	21A
SPRS	Alphabetic request for SPARES output	21
SR	Intermediate value used to calculate ST	
SSTIME(I,J)	System/subsystem allowable sustained downtime	16,17
ST	Intermediate time	
STEPHAS	Accumulated phase time	
SUMX	Total simulation time	

SUMX2	Sum of SUMX squared (for variance calculation)	
SX	Spares multiplier	
T	Duration of phase	
TABORT	Time of abort	
TACMMH	Total average corrective maintenance manhours/mission	
TAD1	Same as SSTIME	
TAD2	Mission allowable downtime	7
TAFM	Total average failures per mission	
TDEOP	Time down at end of phase	
TDOWN	Time system went down	
TIMA(I)	Cumulative phase time	
TIME	Simulation clock time	
TITLE(K,N)	Alphabetic subsystem title	
TNMI	Real value of INMI(JBB)	
TOTAL	Number of failed missions	
TR	Temporary variable used to find maximum unavailability/reliability	
TRR	Same as TR	
TP	Same as TIME	
TTEMP	Downtime	
TTF	Time for failure	
TTR	Time to repair	
TT1	Phase length	
TT2(JBB)	Cumulative time of phase lengths	
TT3	Cumulative phase times	

TYCOON(I)	Downtime for equipment	
TYCUM	Unavailability	
TYCUM2	Percent unavailability	
T1	SSTIME(, ,1)	
T3	Downtime	
T3SUM	Cumulative downtime	
U	Duty cycle utilization	8
UNAVA	Unavailability	
UNREL	Unreliability	
UP1	Time system up in phase	
UP2(JBB)	Cumulative system uptime	
UP3	Cumulative system uptime	
UP4	Cumulative system uptime	
V	Administrative delay time (tender to ship)	8
VAR	MTBMF variance	
VDC(I)	Duty cycle utilization during each phase	9
VMTTR(I,J)	Variable mean time to repair	10
W	Administrative delay time (depot to ship)	8
X	Various; XMTBF; event indicator (+ fail; - repair)	
XAV	Instant availability	
XAVI	Instant availability	
XCUM	Successful missions in last 50	
XDWN	Number of mission failures (XNUM-XTCUM)	
XIAUPP	Real of IAUP	

XIAUPI	Real of IAUPI	
XID	Alphabetic ID	
XIFF	Real of IFF	
XIRR	Real of IRR	
XK	Standard deviation for lower confidence limit 2	2
XKAA	Real of KAA	
XLCLA	Lower confidence limit of 90 percent	
XM	XMTBF Multiplier	7
XMDT	System man down time	
XMTBA	Mean time between mission failures	
XMTBF	Mean time between failures	8
XMTTR	Mean time to repair	8
XMUT	System mean up time	
XM1	Same as XT	
XNO	Number of non aborts	
XNUM	Real of NUM (total missions run)	
XPCAP	Reliability	
XPLCL	Lower confidence limit	
XT	XMTBF multiplier	7
XTABT(I)	Time of abort mission I	
XTCUM	Cumulative successful missions	
XXT(I)	Phase type (I odd); Duration (I even)	3
XXX	XMTBF or VMTTR	
X2	X squared	
Y	Same as XMTTR	
YD	Truncation line accept	21A

APPENDIX C

SPARES SUBROUTINE VARIABLE LIST

CUT	FLSIP cut point
DUM	Dummy variable
EX90DD	Expected 90 day demand
ITMPOP(I)	Number of equipment type I in reliability block diagram
K	Counter
KFACT	K factorial
PRBSUM	Poisson probability summation
SPR1-14	Various user defined input variables

APPENDIX D

MODIFICATIONS TO TIGER PROGRAM INPUT

To use the GAMMA and DEMO options, the end of the main section of the program must be changed to the following:

```
1210 IF (GMMA.EQ.BLNK) GO TO 1230
1220 CALL GAMMA
1230 CONTINUE
      IF (DMNO.EQ.BLNK) GO TO 1240
      CALL DEMO
1240 STOP
      END
```

Subroutine GAMMA, function GAMF, subroutine DEMO, function CHISQ, subroutine TGEN, and subroutine CKTP must be added to the program deck (note: none of these have been utilized or verified for use on the NPS computer).

The following changes were made to the original input deck:

Card 2 - INREJ replaced by ISEED; the random number generator seed.

Card 14 - If spares subroutine is desired, enter 999. for SX. Fourteen variables (SPR1, SPR2, ..., SPR14) may then be read into the spares subroutine in F4.0 format starting in column 25.

These changes are incorporated into the input requirements shown on the following pages. They should be used when preparing the TIGER data input deck.

All integer fields must be right justified

<u>Columns</u>	<u>Format</u>	<u>Variable Name</u>	<u>Description</u>
----------------	---------------	----------------------	--------------------

(1) Timeline Iteration Card

1-4	I4	JCC	No. of timeline variations to be run for the data deck. If JCC exceeds 1, only phase type and duration card(s) must be added in the back of the data deck, followed by a blank card.
5-80	19A4	RUNID	Alphanumeric run identifier.

(2) Statistical Parameter Card

1-4	I4	NMAX	Maximum number of missions to be run (should be in multiples of 50 and must not exceed 1000)
5-8	I4	NOPT	Optimal number of missions (not to exceed NMAX).
9-12	F4.0	PL	Specification requirement for reliability.
13-16	F4.0	XK	Standard deviation to be used in calculating lower control limit.
17-20	I4	ISEED	Random number seed.
21-24	I4	NPH	No. of phase types--not to exceed 6.

NOTE: - If a predefined fixed number of missions is to be run, set PL =1.0, and NOPT and NMAX to the desired number of missions.

<u>Columns</u>	<u>Format</u>	<u>Variable Name</u>	<u>Description</u>
(3) <u>Phase Type and Duration Card(s)</u>			
1-2	F2.0	XXT(1)	Phase type number for first simulation sequence.
3-10	F8.0	XXT(2)	Duration of first sequence.
11-12	F2.0	XXT(3)	Phase type number for second simulation sequence (if any).
13-20	F8.0	XXT(4)	Duration of second sequence.
21-22	F2.0	XXT(5)	Phase type number for third simulation sequence (if any).
23-30	F8.0	XXT(6)	Duration of third sequence.
31-32	F2.0	XXT(7)	Phase type number for fourth sequence (if any).
33-40	F8.0	XXT(8)	Duration of fourth sequence.
41-42	F2.0	XXT(9)	Phase type no. for fifth sequence (if any).
43-50	F8.0	XXT(10)	Duration of fifth sequence.
Note: If more than 5 phase sequences are needed, continue on additional cards using the same fields. No more than 95 phase sequences are permitted.			

(4) *****Blank Card*****

<u>Columns</u>	<u>Format</u>	<u>Variable Name</u>	<u>Description</u>
(5) <u>Printout Option Card</u>			
1-4	I4	KOPT	Printout option switch = 1 for management summary printout. = 2 for engineering summary printout. = 3 for TIGER complete details printout. (For debugging only) = 4 to suppress printout of input data. = 5 to specify printout using the KS variables (see below) = 6 for TIGER/MANNING complete details printout. (For debugging only).
If KOPT=5, select from the following output options as needed (otherwise leave the field(s) blank):			
5-8	I4	KS(1)	= 1: Input Data
9-12	I4	KS(2)	= 1: equipment down at time of mission failure.
13-16	I4	KS(3)	= 1: down time at end of phase.
17-20	I4	KS(4)	= 1: abort messages.
21-24	I4	KS(5)	= 1: all events.
25-28	I4	KS(6)	= 1: ETIME Matrix. (For debugging only.)
29-32	I4	KS(7)	= 1: Not used.
33-36	I4	KS(8)	= 1: Not used.
37-40	I4	KS(9)	= 1: Not used.
41-44	I4	KS(10)	= 1: System & subsystem status.
45-48	I4	KS(11)	= 1: TIGER/MANNING denugging printout.

<u>Columns</u>	<u>Format</u>	<u>Variable Name</u>	<u>Description</u>
----------------	---------------	----------------------	--------------------

Printout Option Card (Cont.)

49-52	I4	KS(12)	= 1: Status of all groups
53-56	I4	KS(13)	= 1: Downtime message.

(6) Phase Repair Card

1-4	I4	IFLAG(1)	Repair option for each phase type, up to 6: = 0 if on-board repair allowed in the phase. = 1 if no on-board repair allowed. = 2 if on-board repair allowed but failure inhibited.
5-8	I4	IFLAG(2)	
9-12	I4	IFLAG(3)	
13-16	I4	IFLAG(4)	
17-20	I4	IFLAG(5)	
21-24	I4	IFLAG(6)	

(7) Repair Policy Card

1-4	F4.0	REPOL	Decimal fraction of repairs to be performed aboard ship, i.e. organizational level.
5-12	F8.2	TAD2	
13-16	F4.0	XM	Mission allowable downtime
17-20	F4.0	XT	MTBF Multiplier. Default = 1.0
			MTTR Multiplier. Default = 1.0

<u>Columns</u>	<u>Format</u>	<u>Variable Name</u>	<u>Description</u>
(8) <u>Equipment Type Cards (one card for each equipment type)</u>			
1-4	I4	I	Equipment type numbers - should be assigned sequentially starting at 1, not to exceed 200.
5-20	4A4	F1	Equipment type description/nomenclature.
21-28	F8.0	XMTBF	Mean time between failure (MTBF).
29-32	F4.0	XMTR	Mean time to repair (MTR). Precede by negative sign and include the variable MTR card if variable MTR option desired. Non-repairable is indicated by a value of 9999.
33-36	F4.0	U	Duty cycle/Utilization (non-zero decimal fraction).
37-40	F4.0	V	Administrative delay time from tender to ship.
41-44	F4.0	W	Administrative delay time from depot to ship.
45-48	I4	IUI	If a variable duty cycle (VDC) for this equipment type is desired, assign a sequential number (between 1 and 50) and include the VDC card following. Otherwise leave this field blank.

<u>Columns</u>	<u>Format</u>	<u>Variable Name</u>	<u>Description</u>
----------------	---------------	----------------------	--------------------

(9)	<u>Variable Duty Cycle (VDC) Card</u>		(Optional - If IUI on previous type card is non-zero, place this card immediately behind the type card to which it refers. A maximum of 50 VDC cards per deck are allowed.)
-----	---------------------------------------	--	---

1-4	I4	IV	VDC Identifier-sequential number, same as the value of IUI on the preceding equipment type card.
-----	----	----	--

5-8	F4.0	VDC(1)	Duty cycle/utilization of the equipment type during each phase type 1-6. These values override the value of U on the preceding Equipment Type Card.
-----	------	--------	---

9-12	F4.0	VDC(2)	
------	------	--------	--

13-16	F4.0	VDC(3)	
-------	------	--------	--

17-20	F4.0	VDC(4)	
-------	------	--------	--

21-24	F4.0	VDC(5)	
-------	------	--------	--

25-28	F4.0	VDC(6)	
-------	------	--------	--

(10)	<u>Variable Mean Time to Repair (MTTR) Card</u>	(Optional - If XMTTR is negative on the Equipment Type Card place this card behind the VDC Card or, if there is no VDC Card, behind the Equipment Type Card.)
------	---	---

1-4	F4.0	VMTTR(1)	MTTR values of the equipment type during each phase type 1-6. Non-repairable is indicated by 9999.
-----	------	----------	--

<u>Columns</u>	<u>Format</u>	<u>Variable Name</u>	<u>Description</u>
----------------	---------------	----------------------	--------------------

Variable Mean Time to Repair (MTTR) Card (Cont.)

5-8	F4.0	VTTR(2)	
9-12	F4.0	VTTR(3)	
13-16	F4.0	VTTR(4)	
17-20	F4.0	VTTR(5)	
21-24	F4.0	VTTR(6)	

(11) *****Blank Card***** (This indicates the end of the equipment type cards.)

(12) Equipment Cards (One for each equipment type - Place sequentially by type number)

1-4	I4	NTYPE	The type number associated with the equipment listed in the next field(s).
5-8	I4	LOAD(1)	Equipment numbers of those equipment which belong to the designated equipment type -
9-12	I4	LOAD(2)	up to 19 equipment per card (if there are more than 19 equipment associated with a given type, use additional equipment cards and repeat the same type number). The largest equipment number allowed by the program is 500. The total number of equipment must not exceed 500. No gaps are allowed between equipment number 1 and the largest assigned equipment number.
13-16	I4	LOAD(3)	
17-20	I4	LOAD(4)	
21-24	I4	LOAD(5)	
25-28	I4	LOAD(6)	
29-32	I4	LOAD(7)	

<u>Columns</u>	<u>Format</u>	<u>Variable Name</u>	<u>Description</u>
----------------	---------------	----------------------	--------------------

Equipment Cards (Cont.)

73-76	I4	LOAD(18)	
77-80	I4	LOAD(19)	

(13) *****Blank Card***** (This indicates end of equipment cards.)

(14) Blank Card or literal "UNLIMITED SPARES" starting in column 1. If Blank Card is used then the spares multiplier (SX) may be inserted in Col. 21-24. The format for SX is F4.0 and the default value is 1.0; Use 999. to call SPARES subroutine. Variables SPRI-SPR14 may be inserted in F4.0 format starting in Col. 25.

<u>Columns</u>	<u>Format</u>	<u>Variable Name</u>	<u>Description</u>
(15) <u>Spares Cards</u>	(Omit if unlimited spares specified above. One spares card for each equipment type-program assumes these cards are in sequential order starting with Type 1)		
1-4	I4	ISPARE(1)	Number of organizational level spares (on-board) for the equipment type.
5-8	I4	ISPARE(2)	Number of spares at the tender for the equipment type.
9-12	I4	ISPARE(3)	Number of spares at the base (depot) for the equipment type.

66

NOTE: For each phase type, a set of the remaining cards (except the optional output and demo cards which appear once) must be placed consecutively in the data deck.

(16) <u>System Card</u>			
1-4	A4	ID	Any alphanumeric, e.g., the literal "SYST"
5-8	I4	LL	Phase type number (sequential) - Maximum value is 6.
9-12	I4	NSS	Number of subsystems in the phase (varies only from 1 to 31)
13-16	I4	ISS	System identification number (usually last group number on the configuration matrix cards).

<u>Columns</u>	<u>Format</u>	<u>Variable Name</u>	<u>Description</u>
<u>System Card (Cont.)</u>			
17-24	F8.0	SSTIME	System allowable sustained down time TAD1 (should not be less than subsystem TAD1 values). This value should be less than or equal to TAD2 (Repair Policy Card). To inhibit aborts use a value of 100000.
<u>(17) Subsystem Cards (One for each subsystem - up to 31.) At least one subsystem is required.</u>			
1-4	A4	ID	Any alphanumeric, e.g., the literal "SS1", "SS2", ... "SS31".
5-8	I4	LL	Phase type number.
13-16	I4	ISS	Subsystem identification number. This is a group number for a group defined on a Configuration Matrix Card (see below). Each designated subsystem group must be a group that, upon its failure, causes the system to fail.
17-24	F8.0	SSTIME(2)	Subsystem allowable sustained down time (TAD1). This value should be less than or equal to SSTIME on the System Card. To inhibit aborts use a value of 100000.

<u>Columns</u>	<u>Format</u>	<u>Variable Name</u>	<u>Description</u>
----------------	---------------	----------------------	--------------------

(18) <u>Configuration Matrix Cards</u> (One card for each group, up to 300 cards)			
1-4	I4	NRO	The number of members in the group defined on this card that are required to be operating and in an upstate.
5-8	I4	IB(1)	The group number assigned to the group of members defined on this card. It may vary from 501 to 1000 in any order.
9-12	I4	IB(2)	The numbers of the equipment and groups which make up the group defined on this card. The maximum number of members in a group is unlimited; however, if there are more than 7, a continuation card is required, which is of the same format. The number required and master group number must be identical on all continuation cards.
13-16	I4	IB(3)	
17-20	I4	IB(4)	
21-24	I4	IB(5)	
25-28	I4	IB(6)	
29-32	I4	IB(7)	
33-36	I4	IB(8)	

(19) <u>Equipment Operating Rule Cards</u>			
(Optional - Usually this card is placed immediately behind the configuration matrix card which refers to the equipment and groups on this card.)			
These cards indicate the equipment operating rules for string or standby equipment. The string equipment operating rule causes shutdown of a designated series equipment upon failure of any of the other equipment or equipment groups on the card. The standby			

<u>Columns</u>	<u>Format</u>	<u>Variable Name</u>	<u>Description</u>
----------------	---------------	--------------------------	--------------------

Equipment Operating Rule Cards (Cont.)

equipment operating rule causes designated equipment to be energized upon failure of any of the other equipment or equipment groups on the card. The maximum number of equipment operating rules is 49. (One rule defined per card.)

The designated equipment number. If it is a standby equipment, it must be preceded by a minus sign.

The other equipment or equipment group numbers.

Place any non-zero integer in this field (to distinguish Equipment Operating Rule Cards from Configuration Matrix Cards).

1-4	I4	ISTB(1)	
5-8	I4	ISTB(2)	
9-12	I4	ISTB(3)	
13-16	I4	ISTB(4)	
17-20	I4	ISTB(5)	
21-24	I4	ISTB(6)	
25-28	I4	ISTB(7)	
29-32	I4	ISTB(8)	
33-36	I4	ISTB(9)	
37-40	I4	ISTB(10)	
41-44	I4	IRULE	

<u>Columns</u>		<u>Format</u>	<u>Variable Name</u>	<u>Description</u>
(20)	*****Blank Card***** (This indicates end of phase configuration and operating rules.)			
(21)	<u>Optional Output Card</u> (Optional - Appears once in computer job deck)			
1-4	A4	SPRS		Place any alphanumeric, e.g., "SPR", in this field if a table of spares usage is desired.
5-8	A4	APPL		Place any alphanumeric, e.g., "APL", in this field if a summary table of equipment that caused mission failures (unreliability) and system down times (unavailability) is desired.
9-12	A4	GMA		Place any alphanumeric, e.g., "GMA", in this field if the gamma distribution output is desired.
13-16	A4	DEMO		Place any alphanumeric, e.g., "DEMO", in this field if a sequential probability ratio test plan for the system being analyzed is desired. If this option is exercised, an additional card, 21A, is required.
(22)	<u>DEMO Information Card</u> (Optional - must be included if DEMO is specified on the Optional Output Card.)			
1-4	F4.0	A		Producer Risk.
5-8	F4.0	B		Consumer Risk

<u>Columns</u>	<u>Format</u>	<u>Variable Name</u>	<u>Description</u>
----------------	---------------	----------------------	--------------------

DEMO Information Card (Cont.)

9-12	F4.0	R	Discrimination Ratio.
------	------	---	-----------------------

The following are optional inputs:

13-16	F4.0	HAD	X-Axis accept intercept (Delta).
17-20	F4.0	HRD	X-Axis reject intercept (Delta).
21-24	F4.0	YD	Trucation line accept (Delta).
25-28	F4.0	SLD	Slope (Delta).
29-32	I4	KD	Truncation line reject (Delta).
33-36	I4	ITIME	Number of sets (explained in Appendix C).
37-40	I4	ITER	Number of simulations per set.
41-44	I4	N	Random number initializer.
